Making an Optimum Recording

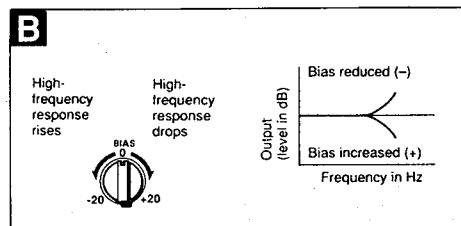

Bias and Recording Level Calibration

There are many different types of cassettes on the market, each with varying magnetic properties. Although your unit is equipped with the ATS (Automatic Tape Selection) system which sets the appropriate equalization characteristics and bias current for each tape type, an additional calibration adjustment can often produce even better results. Use the bias current and recording level calibration function to obtain the optimum recording conditions for your tape.

Bias calibration

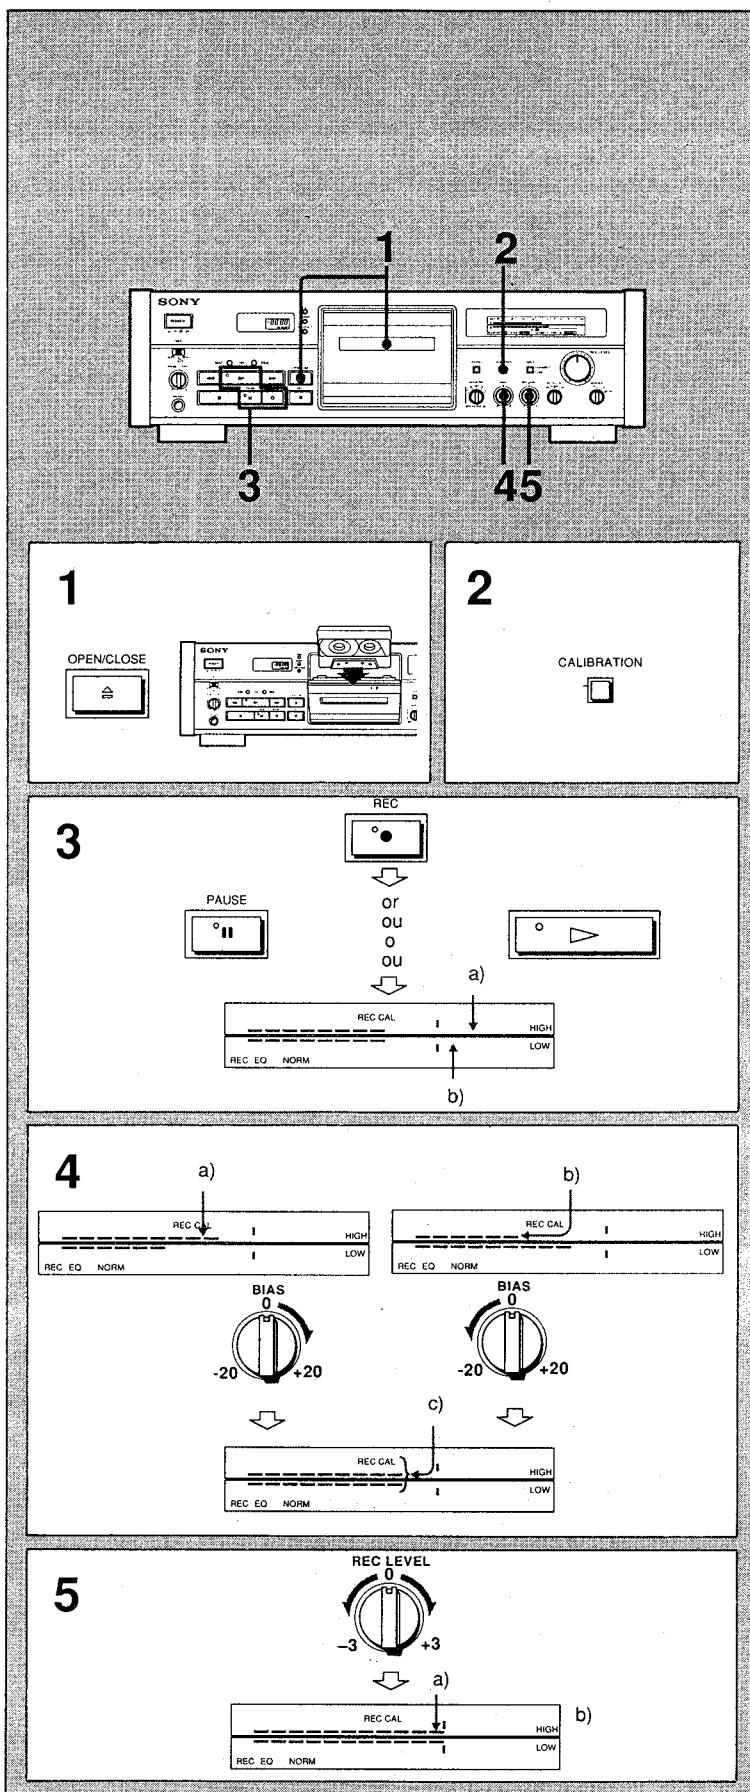

Choosing the optimum bias current for a tape ensures minimum distortion and flat frequency response. Lowering the bias current boosts high-frequency response, but also results in higher distortion. Raising the bias, on the other hand, reduces distortion, but also dampens high-frequency response. Optimum bias is thus obtained when the bias current and high-frequency response are well balanced.

- If the bias current is higher or lower than the optimum setting for a certain tape, the frequency response changes as shown in the Chart in Fig. B. Changing the bias can thus be used to tailor the response to your liking, for example by slightly emphasizing the upper or lower end.
- The frequency response of metal tapes is much less affected by changes in the bias current than other tape types. With some tapes, the adjustment range of this deck (±20%) may therefore not be sufficient to cover every possible requirement.

Recording level calibration

Even when the recording level is adjusted correctly, using a tape with low sensitivity will result in a low playback level. The REC LEVEL calibration control allows you to compensate for sensitivity differences among tapes to equalize both recording and playback levels. This is especially important when using the Dolby NR system, since it is most effective when recording and playback levels are the same.

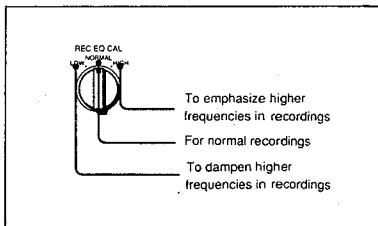

Making an Optimum Recording

- 1 Insert the cassette to be used for recording.
- 2 Press CALIBRATION.
- 3 Press **●**, then **II** or **►** to activate the recording test tone.
 - a) Playback level for an 8-kHz signal
 - b) Playback level for a 400-Hz signal
- 4 Adjust BIAS until both meters indicate equal playback levels.
 - a) A high reading on the upper meter indicates a low bias current.
 - b) A low reading on the upper meter indicates a high bias current.
 - c) An equal reading on both meters indicates the optimum bias current condition.
- 5 Adjust REC LEVEL CALIBRATION until both meters reach the recommended level (REC CAL).
 - a) Recommended level
 - b) The bias current is now adjusted to the optimum level and the tape sensitivity compensation has been set. Press **■**, then set CALIBRATION to OFF. Rewind the tape and start the actual recording.

Making an Optimum Recording

Recording Equalization Calibration

Although bias current and equalization are automatically set by the Automatic Tape Selection (ATS) function for the tape being used, you can use the REC EQ CAL switch to change the recording characteristics according to the nature of the source material or to compensate for the particular characteristics of the tape.

Bias Calibration Recording

Use the REC EQ CAL switch in conjunction with the BIAS control to modify bands of sound and record according to the tape's characteristics.

- When recording music which has strong middle and low frequencies**
Set the bias at flat with the REC EQ CAL switch set in the HIGH position to increase the bias current.
Adjust the BIAS control so that the HIGH and LOW meters indicate equal readings.
- When recording music which has strong high frequencies**
Set the bias at flat with the REC EQ CAL switch set in the LOW position to decrease the bias current.
Adjust the BIAS control so that the HIGH and LOW meters indicate equal readings.

Note

With metal tape, because the amount of frequency characteristic modulation is not in proportion to that of the bias, the optimum bias current may not be obtained using the methods above.

Another use of the REC EQ CAL switch

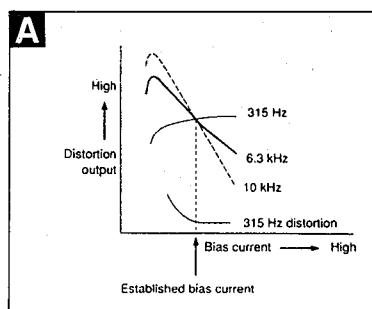

When using special tapes, adjusting the BIAS control with the REC EQ CAL switch set in the NORMAL position may not result in equal readings on the HIGH and LOW meters. If this occurs, adjust the BIAS control after setting the REC EQ CAL switch to HIGH or LOW.

Recording

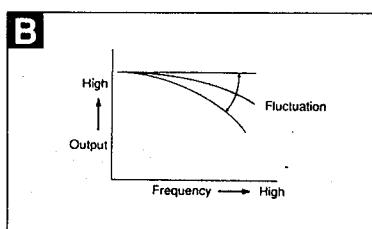

What is the Dolby HX PRO System?

The Dolby HX PRO system provides improved linearity in high-range frequency response during recording. Tapes recorded with this system retain the same high quality even when played back on other tape decks.

As shown in Fig. A, characteristics such as output level and distortion differ widely according to the bias (high-frequency) current.

In conventional systems (see Fig. B), the bias current is susceptible to variations in certain recording signals which may cause fluctuations in frequency response, distortion, or other unwanted characteristics.

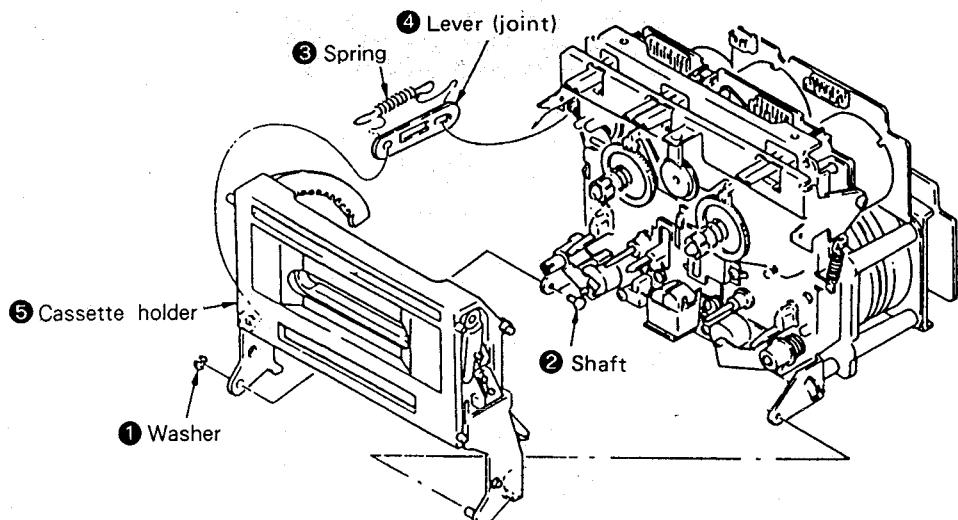

With the Dolby HX PRO system, the effective bias amount added to the bias current is controlled in millisecond units to greatly reduce distortion, improving linearity in high-range response and ensuring high-intensity recording with minimal distortion and noise.

record/playback head	pinch roller
erase head	rubber belts
capstan	idle

2. Demagnetize the record/playback and erase head with a head demagnetizer.

3. Do not use a magnetized screwdriver for the adjustments.

4. After the adjustments, apply suitable locking compound to the parts adjusted.

5. The adjustments should be performed with the rated power supply voltage unless otherwise noted.

4. WS-48B(3 kHz, 0 dB)

5. P-4-A100(10kHz, -10dB)

Definition of Terms: The figures are of a record/playback head.

Tape Path Adjustment

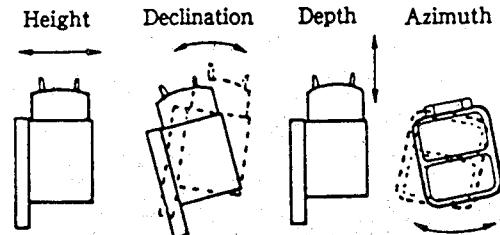

• Refer to Adjustment Position on page 12.

Note: When using the adjustment methods for other than replacement reasons, please do not tamper unnecessary with the adjustment screws or the erasehead because either the supply pinch roller guide or the record/playback head will be made the standard tape paths. Moreover, when it is necessary to adjust and replace two or more of any of the heads and/or pinch rollers, replace them one by one, completely taking out first tape path, and then replacing second one.

Preparation:

1. Mirror cassette CQ009C 8-909-708-01
(or CQ012C 8-909-708-02)

If one does not have this, cut out the sections of a 120-minute cassette shell as indicated below and use that cassette.

Adjustment method:

Supply Pinch Roller

Note: Only perform this adjustment when the supply pinch roller is to be replaced.

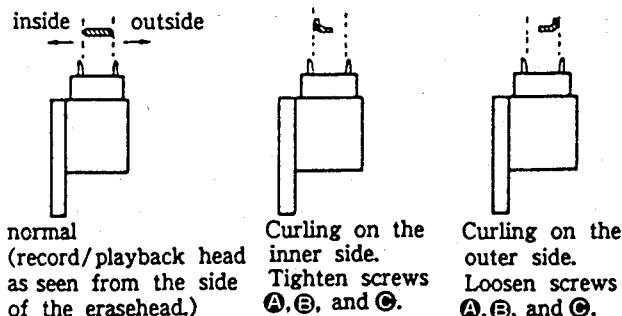

1. Insert the mirror cassette and put the unit in record/playback mode.
2. Check to see whether the tape is curling at the record/playback head guide or the pinch roller guide. If it is curling, remove the curl by adjusting the **(1)** tape curl adjustment screw. Then, check that the tape is running past the middle of the erasehead.

Record/playback Head

Note: Only perform this adjustment when the record/playback head is to be replaced.

1. Insert the mirror cassette and put the unit in record/playback mode.
2. **(Height Adjustment)** Check to see if the tape is curling at the tape guide of the head. If it is curling, tighten screws **(A)**, **(B)**, and **(C)**, respectively by the same angle, moving the head so that it remains at the same angle throughout the

procedure. If it curls on the bottom side of the mirror cassette (actually the inner side), tighten all the screws equally; but loosen them if the tape begins to curl on the top side (other side).

3. **(Declination Adjustment)** While in the record/playback position, set the back tension to 0 (wind the supply reel with something thin like a pencil in counterclockwise direction) and make sure there is no curling or shifting (shifting up/shifting down) at the guide of the record/playback head. Because shifting can only occur due to a difference in the width of the tape and that of the tape guides (curling will otherwise occur), it is necessary to pay close attention since it can be easily overlooked.

When there is a shift, tighten screws **B** and **C** equally and change the declination of the head. If the tape is shifting up, tighten the screws, and if it is shifting down, loosen them.

4. Repeat the adjustments in steps 2 and 3 and fine adjust the height and the declination.

5. **(Preliminary Azimuth Adjustment)**

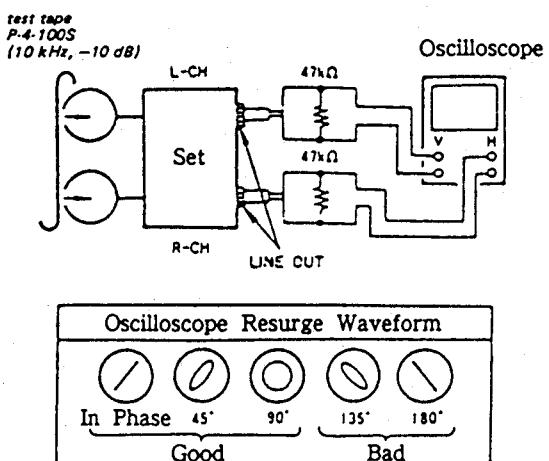

After demagnetizing and cleaning the adjustment head, play back WS-48B (3kHz, 0dB).

Turn screw **C** so that the reading on the level meter of the unit or that of the level meter connected to LINE OUT is maximized.

If the screw is turned at least half a revolution, repeat the adjustments from step 1.

6. **(Tape Path Check)** Connect the oscilloscope to LINE OUT and play back P-4-A100 (10kHz, -10dB) to display a surge waveform. After 20 seconds of record/playback (after the tension within the loop has been increased sufficiently), make sure the variation in the surge is within ± 45 degrees (within ± 45 degrees is desired).

If the variation is greater than this, it is because the declination and/or the height adjustment is not perfect. Repeat the adjustment from step 1.

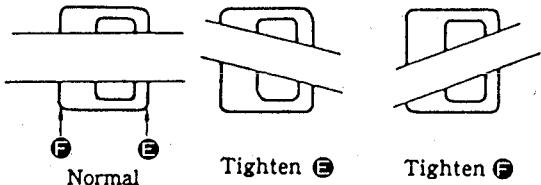

Erasehead

Note: Only perform this adjustment when the erasehead is to be replaced.

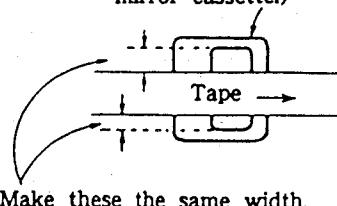

1. Insert the mirror cassette and put the unit in record/playback mode.

2. **(Azimuth Adjustment)** Adjust the azimuth of the erasehead by adjusting screws **E** and **F** so that the runs as evenly as possible.

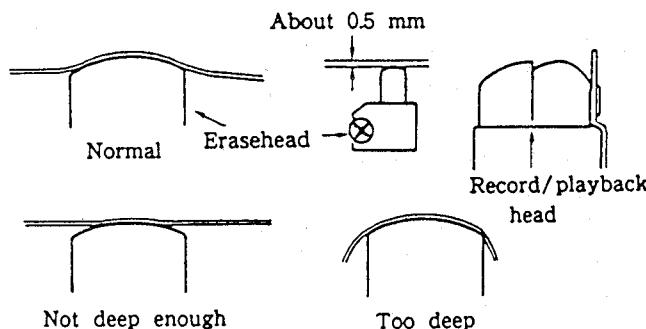

3. **(Height adjustment)** Turn screws **D**, **E**, and **F** all by the same angle so that the portions of the erasehead visible at top and bottom are nearly of equal width. If the width at the top is greater, tighten the screws; if the width at the bottom is greater, loosen the screws.

Erasehead (The erasehead as seen through the mirror cassette.)

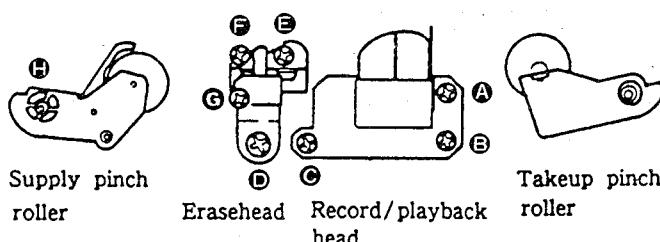

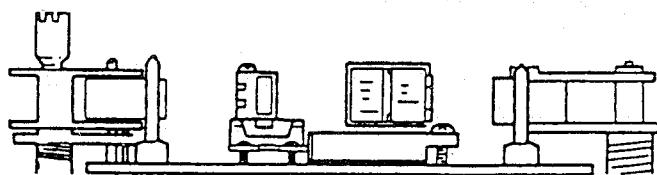

- (Declination Adjustment) Leaving it in the playback position, put the back tension to 0 and make certain the erasehead part and supply pinch roller guide part do not shift. If there is a shift, turn the screw **D** and change the declination. Looking at it using the mirror cassette, if the tape shifts up, tighten the screw, and if it shifts down, loosen the screw.
- Repeat the adjustments beginning with step 2 and fine adjust the height and declination. And make sure the tape does not curl up on the pinch roller guide or the guide part of the record/playback head.
- (Depth Adjustment) In order to make the entire head play the tape smoothly, and to make sure the depth of the erasehead is neither too shallow nor too deep, loosen screw **C** a bit.

Check

- Check to make sure that there are no curls or shifts throughout the whole tape path and that the tape runs smoothly.
- Reapply the locking compound to the adjusted screws. (The locking compound should only be applied to screw **C** after the azimuth has been adjusted.)

Adjustment Position: As seen from the cassette, side (top) and MD as seen head on (bottom).

Pinch Roller Pressing Force Measurement

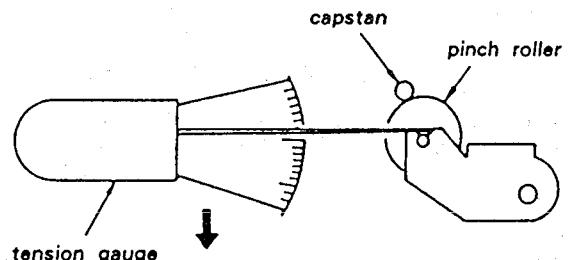

Mode: playback

5. Adjust RV104(L-CH) and RV204(R-CH) so that the difference between the playback output at 10kHz when the HXPRO is ON and that of 10kHz when ON is within 0.5dB to -0.5dB.

Meter Level Adjustment**Setting:**

REC LEVEL knob: standard record position.
(See page 12.)

Procedure:

1. Stop mode

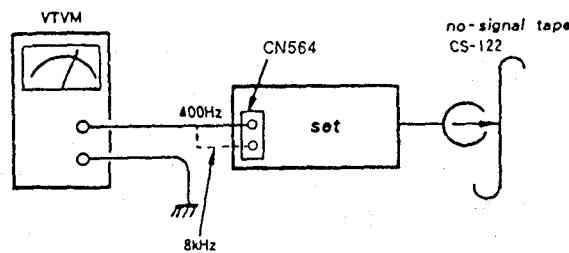

2. Adjust RV107(L-CH) and RV207(R-CH) so that a reading of the meter is set to OVU and the lamp is lit.

3. Adjust REC level so that the LINE OUT level is set to +10dB and check that all the lamps are lit.

Calibration OSC and Calibration Meter Adjustment**Setting:** CALIBRATION switch: ON**Procedure(OSC OUT LEVEL):**

1. Mode: record(no-signal(LINE INPUT))

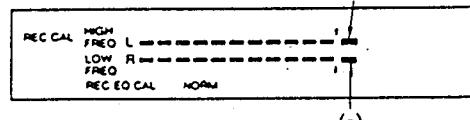

2. Adjust RV504 so that a check-point level at 400Hz is +10dB.
3. Adjust RV503 so that a check-point level at 8kHz is +10dB.

Procedure(CAL METER ADJ):

1. Put the set in record mode and adjust RV208(HIGH) so that HIGH FREQ segments in the CAL LEVEL meter light thoroughly up to OVU as shown in the figure below. Segment(a) may flicker.

2. Preset RV108(LOW) so that segment(a) in LOW FREQ CAL LEVEL meter lights. Then adjust RV204 to the point where segment (a) goes out.

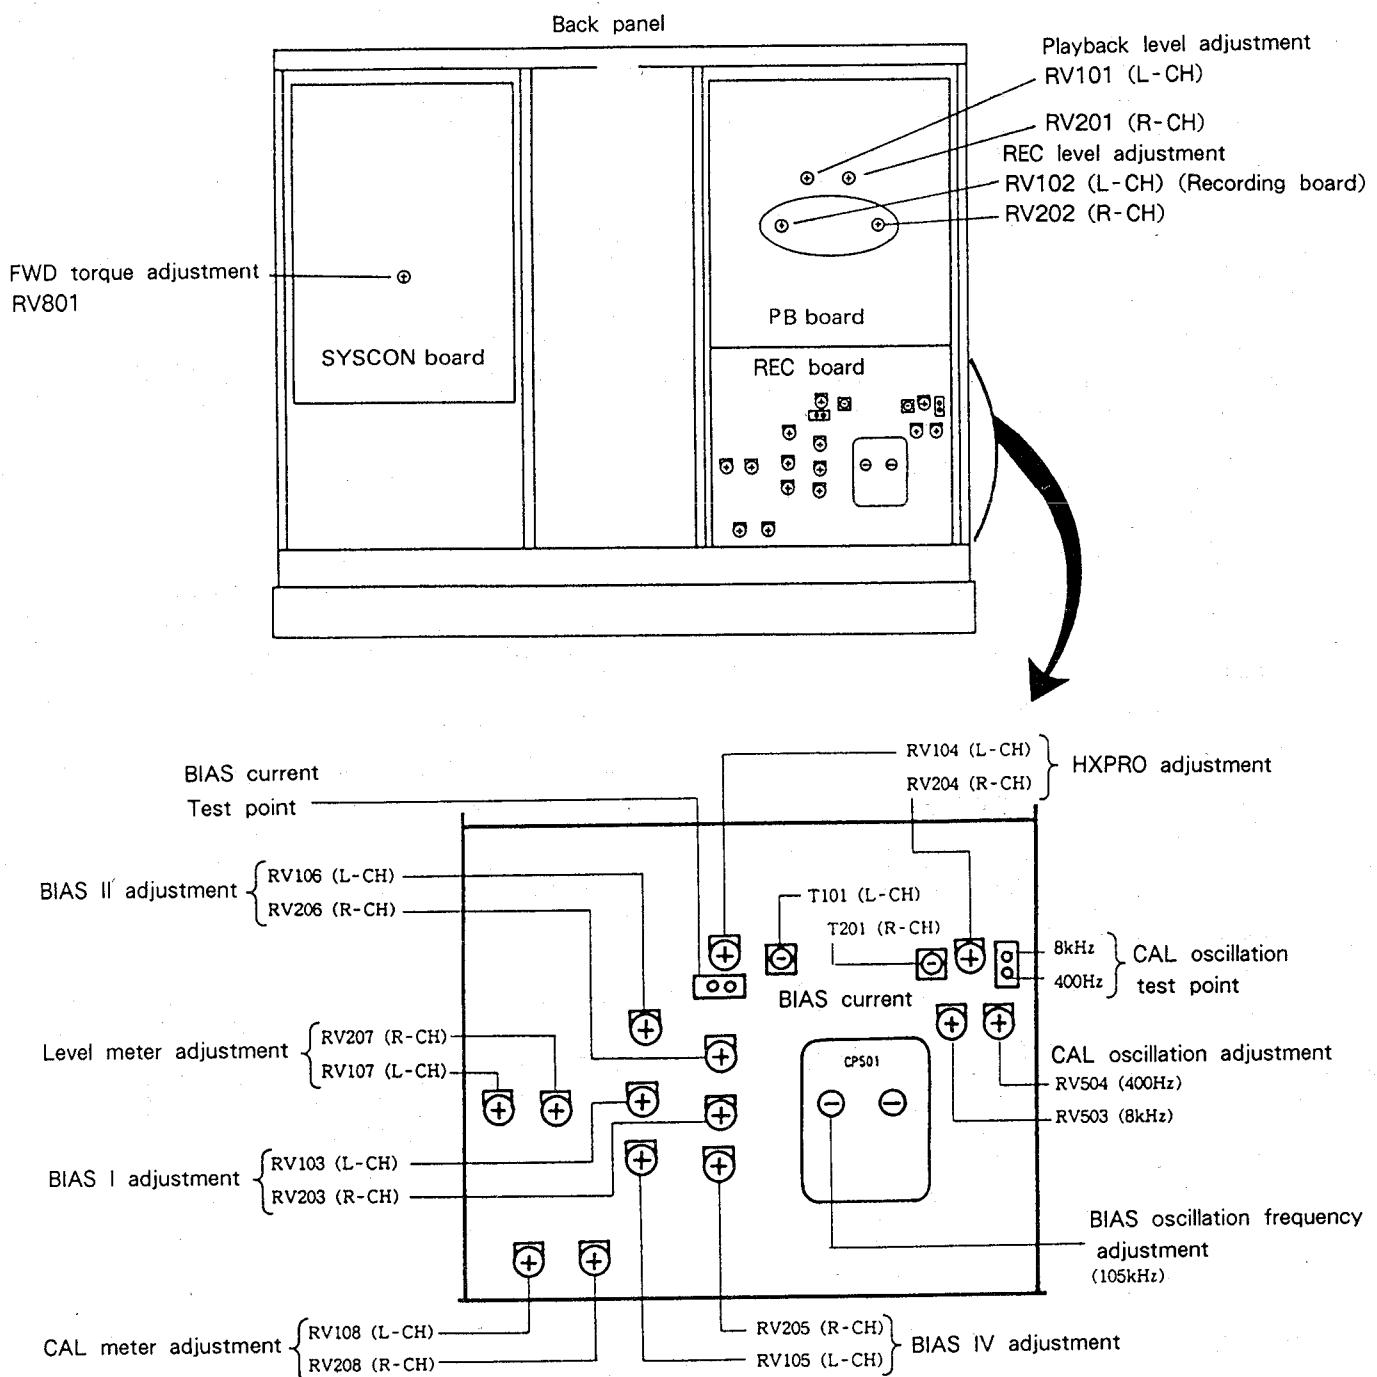

HIGH : LEVEL (a) may flicker.

(a)

LOW : LEVEL (a) must not flicker.
